- Page 40 #2. Consider  $\phi : G \rightarrow H$  an isomorphism. Let  $x \in G$  with  $|x| = n$ . This means  $x^n = 1_G$ . Therefore  $\phi(x^n) = \phi(1_G)$ , and since  $\phi$  is an isomorphism we have  $\phi(x)^n = 1_H$ . So the order of  $\phi(x)$  is at most  $n$ .

To prove the order is equal to  $n$  suppose there is a  $k < n$  for which  $\phi(x)^k = 1_H$ , this means  $\phi(x^k) = 1_H$  and that  $x^k = \phi^{-1}(1_H)$ . Finally  $x^k = 1$  which contradicts  $|x| = n$ . So  $|\phi(x)| = |x|$ .

If  $\phi$  is only a homomorphism we don't get this result. Take  $\phi : (\mathbb{Z}, +) \rightarrow (\mathbb{Z}_2, +)$  by  $\phi(x) = x \bmod 2$ .  $\phi$  is a homomorphism but  $|1| = \infty$  and  $|\phi(1)| = 2$ .

- Page 40 #3. Let  $\phi : G \rightarrow H$  be an isomorphism. Consider  $a, b \in G$ . We have  $\phi(a)\phi(b) = \phi(ab) = \phi(ba) = \phi(b)\phi(a)$ . So  $\text{Im}(\phi)$  is commutative. Because  $\phi$  is a bijection we have  $\text{Im}(\phi) = H$ , so  $H$  is abelian.

For the other direction note that  $\phi^{-1}$  is also an isomorphism, and therefore if  $H$  is abelian then  $G$  will be abelian by the same argument.

More generally, if  $\phi : G \rightarrow H$  is a homomorphism and  $G$  is abelian then  $H$  will be abelian provided  $\text{Im}(\phi) = H$ . In other words, so  $\phi$  must be onto to ensure that if  $G$  is abelian, then so is  $H$ .

- Page 40 #4. Consider the multiplicative groups  $\mathbb{R} - 0$  and  $\mathbb{C} - 0$ . Consider, for sake of contradiction, an isomorphism  $\phi : \mathbb{C} - 0 \rightarrow \mathbb{R} - 0$ . Now,  $\phi(i) \in \mathbb{R} - 0$ . Say  $\phi(i) = x$ , then we have  $\phi(i)^2 = x^2$ , which means  $x^2 = \phi(-1)$ .

We will now prove  $\phi(-1) = -1$ . We have  $\phi(-1)^2 = \phi(1) = 1$ . This means  $\phi(-1)$  equals either 1 or -1. If  $\phi(-1) = 1$  then  $\phi(-1) = \phi(1)$  which contradicts  $\phi$  being one to one. So, since  $\phi(-1) = -1$  we have  $x^2 = -1$ , where  $x$  is real. This equation has no solutions over the real numbers, this contradicts  $\phi$  being well defined. Thus the multiplicative groups  $\mathbb{C} - 0$  and  $\mathbb{R} - 0$  are not isomorphic.

- Page 40 #7.  $D_8$  and  $Q_8$  are not isomorphic.  $D_8$  has 4 elements of order 2 (V,H,D,D') while  $Q_8$  has only one element of order 2 (-1).

- Page 40 #17. Let  $G$  be a map and consider the map  $\phi : G \rightarrow G$  by  $\phi(g) = g^{-1}$ .

→ Suppose  $\phi$  is a homomorphism. Consider  $a, b \in G$  then we have  $b^{-1}a^{-1} = (ab)^{-1} = \phi(ab) = \phi(a)\phi(b) = a^{-1}b^{-1}$ . So  $b^{-1}a^{-1} = a^{-1}b^{-1}$  for all  $a, b \in G$ . Thus  $G$  is abelian.

← Suppose  $G$  is abelian. Consider  $a, b \in G$ . We have  $\phi(ab) = (ab)^{-1} = b^{-1}a^{-1} = a^{-1}b^{-1} = \phi(a)\phi(b)$ . Thus  $\phi$  is a homomorphism.
